introduction

Astro Blaster is an electronic game that makes extensive use of digital integrated circuitry and television monitor concepts. This manual is designed for the maintenance technician who possesses a general knowledge of solid state circuitry, microprocessor and digital integrated circuitry, and TV monitor concepts. Any individual **not** knowledgeable in these areas **should not** attempt repair of the electronic portion of the game.

Gremlin's new G-80 system will make troubleshooting easy. Each board has a separate function and most problems can immediately be isolated to a single board. The individual boards contain less circuitry than if they were combined on one or two boards. This results in faster and easier servicing. The new G-80 system gives Gremlin a lot more flexibility in designing new games. Increased ROM capability and the addition of speech means that new Gremlin games will be more exciting and even more profitable. If you have any questions not answered in this manual, call Gremlin/SEGA Customer Service, (714) 277-8700.

game concept

Astro Blaster is a one or two player game in which players must advance through squadrons of alien ships in an attempt to dock with the mother ship. Players move their ship left or right and shoot at attacking squadrons. A special time warp allows the player to slow down the alien space ships and their laser fire, while maintaining his own ship and laser fire at normal speed.

Voice Command

Astro Blaster is Gremlin/SEGA's first video game with speech synthesis. As players go through the game play, each step is directed by the voice of mission control. Mission control keeps players informed of fuel status, provides a countdown on warp, keeps track of the number of ships remaining, and monitors the players' laser temperature.

Game Action

As players enter each new sector they encounter a different number of alien squadrons. Players must destroy all ships in each squadron to pass through the sector. One squadron of rockets is extremely difficult to destroy, but players can pass through this squadron by hitting a few enemy ships. Once a player has destroyed all the squadrons in that sector, he enters an asteroid belt. He must maneuver and shoot his way through the asteroids to reach the mother ship. If fuel is critically low when the player enters the asteroid belt, he can receive extra fuel by shooting the red fireballs interspersed among the asteroids. After passing through the asteroid belt, the player's ship docks with the mother ship and refuels.

Alien Ships

There are 29 different alien squadrons players encounter as they move through the different sectors. Every new sector increases in difficulty with different numbers of squadrons in each sector. Each alien ship has its own individualized sounds, movements and firing capability.

Fuel and Laser Temperature

During their game, players must keep track of fuel consumption. As the player's ship moves through the sector, it consumes fuel. The player must ensure he has enough fuel to advance through the sector and dock with the mother ship. Extra fuel can only be obtained by shooting red fireballs or docking with the mother ship. The screen also displays the laser temperature. As players fire, the laser temperature rises. When they cease firing, it cools down. If the laser overheats, players lose their laser fire until it cools down.

Time Warp

By depressing the warp button, players slow down the enemy ships and their laser fire while maintaining his own at normal speed. Players receive one warp per ship and are awarded one warp upon docking, if he has used his warp in the previous sector.

Scoring

Each alien ship destroyed carries a different point value. Players also receive double points for destroying an alien ship when their fuel is in the red. To add further excitement, there are 25 tasks that a player performs during the course of the game and receives a secret bonus. Players do not know what these tasks are, but a good player will keep track. The 25 tasks are consistent throughout the game. Players also receive a bonus for any fuel they have left when they dock with the mother ship.

With a two-player game, players alternate at the conclusion of each sector, not after each ship. Players receive 3 to 5 ships, which is operator adjustable. The game is over when a player runs out of fuel, loses all his ships or crashes while attempting to dock with the mother ship. The top three scores are displayed and the game ranks players from 1 to 99.

game set-up and inspection

Your Astro Blaster game is ready to play immediately upon arrival. But, **before** you plug in the game, open the rear access panel and make a general inspection of the interior of the game. The following items should be checked to insure no shipping damage has occurred.

1. Inspection

a) Are the fuses intact?

There are five fuses (not counting the monitor fuses which are detailed in the monitor manual accompanying this game). One fuse is located on the AC junction box. The other four are on the power supply PC board.

b) Are the connectors firmly inserted?

Proper connector fittings must be checked before game power is applied. Check all related connectors for good contact. Although disconnected connectors are easily spotted, poor contacts are difficult to locate. The connectors should therefore be pushed in firmly and then loosened to spot poor connections. When testing the PC board connectors, **always** turn off the power.

c) Cabinet Inspection

Inspect the cabinet interior and exterior to ensure that no damage has occurred during shipping. Check to ensure graphics are in place, monitor is not damaged and that the overall cabinet is in good condition.

2. Voltage Selection

Before plugging in your game, make sure that the game voltage is correct for your location. Locate the two leads from the AC junction box to the power transformer. For 100 VAC, they should be connected to terminals 1 and 2 on the power transformer. For 110 VAC, connect 1 and 3, and for 220 VAC applications, they should be connected to 1 and 4.

You will also notice on the AC junction box that there is a safety interlock switch. When the rear panel is in place the switch is depressed and the game receives power. Removing the rear panel, the switch returns to its original position and the power is cut off from the game. For servicing, this switch can be pulled out and power will be restored.

3. Game Specifications

Power	100 VAC, 60 HZ (nominal), 175 watts
	110 VAC, 60 HZ (nominal), 175 watts
	220 VAC, 60 HZ (nominal), 175 watts
Dimensions	25½ inches wide × 28 inches depth (64.77 cm wide × 71.12 cm depth) 67 inches height (170.18 cm height)

4. Important Notes

- a) The following note is included in compliance with FCC rules:
WARNING: This equipment generates, uses, and can radiate radio frequency energy and if not installed and used in accordance with the instructions manual, may cause interference to radio communications. As temporarily permitted by regulation, it has not been tested for compliance with the limits for Class A computing devices pursuant to Subpart J of Part 15 FCC Rules, which are designed to provide reasonable protection against interference in which case the user at his own expense will be required to take whatever measures may be required to correct the interference.

b) Miscellaneous

Never remove circuit board connections while power is on.

Never replace any components with anything other than exact replacement parts

Do Not replace fuses with anything other than the proper value. A blown fuse indicates an overload condition within the game. Replacing the fuse with a higher value can cause severe damage to internal components, if an overload occurs.

G-80 theory of operation

Game Block Diagram

* DENOTES CIRCUITRY CONTAINED IN VIC CHIP.

1. G-80 Boards:

The new G-80 system consists of five boards that plug into a mother board.

They are the CPU, Speech, Sound, Video and EPROM boards. They plug into the mother board in a card cage system to simplify repairs and cut down on interference to outside communications systems. The mother board is cross-wired to allow for the boards to be plugged-in in any order. Listed below are the bus pin assignments on the mother board:

1	Ground	A	Ground
2	A15	B	A7
3	A14	C	A6
4	A13	D	A5
5	A12	E	A4
6	A11	F	A3
7	A10	H	A2
8	A9	J	A1
9	A8	K	A0
10	D7	L	D3
11	D6	M	D2
12	D5	N	D1
13	D4	P	D0
14	WAIT	R	RESET

15	INT	S	EDGINT
16	NMI	T	EXT
17	EXT SEL	U	OUT
18	MEMR	V	MEMW
19	INPUT	W	OUTPUT
20	RFSH	X	MREQ
21	INTACK	Y	AC
22	+5V	Z	+5V
23	+5V	a	+5V
24	-5V	b	-5V

43		y	
44	Ground	z	Ground

* For Development Purposes Only

a) **CPU BOARD** (Refer to CPU Schematic, sheets 6 and 7)

The CPU board is completely timed with the video board. But, for testing purposes it contains its own clock circuit, powered by an 8.000 MHZ crystal. Pin 17 is the external clock select and is grounded when the video board is plugged-in. When the external clock pulse comes in through pin T, it goes directly to the CPU and the entire CPU clock circuit is disabled. The WAIT signal, entering in at pin 14, is used to synchronize slower memory accessed by the CPU. The NMI circuit, entering in at pin 16, contains a switch for activating the built-in self-test. The self-test system will be explained more fully later.

When the edge interrupt circuit, entering at pin S, goes LO, it triggers an interrupt in the CPU. The CPU stops whatever it is working on, completes the activity required by the interrupt, and then returns to the function it was performing prior to the interrupt. It is a negatively triggered interrupt, which can be disabled by the CPU at any time.

The AC signal, entering in at pin Y, combines with RESET at pin R and the input from the reset switch located on the operator panel to reset the CPU. Disregard PANEL RESET at pin 30. This circuit is used only for system development.

The CPU in Astro Blaster is a Z80A. You must always use a Z80A as the Z80 is not fast enough to run the game. U21 is an address bus controller. Eight of the sixteen address lines pass through U21 before addressing the RAMs and the Eprom at U25. U25 contains the data for the self-test and contains features common to all games, such as coin acceptance, credit/coin handling, power-up sequence, player 1 or 2 recognition and CPU initialization. U3 is an output port for the CPU and U4 is the input port. Connector P1, pins 23 through 40, shown on sheet 6 is not used in Astro Blaster. U15, located below U4 on the schematic, decodes memory select on the CPU board. Sheet 7 contains the coin inputs, player inputs and inputs from the operator panel. The coin

circuitry contains ICs U6, U39 and U16. U9 is the input port for the coin switches and service switch. Player inputs enter through connector P1, pins 15 through 22.

b) VIDEO BOARD

The video board contains a VIC chip used in previous games (U58). The video board also contains a 15.468 MHZ crystal that generates the timing signals for video generation. Because the video board contains twice as many video RAMs, it has a more extensive graphics capability. Color capability is greatly expanded because of a color RAM, U9, which allows the program to create a wider variety of color schemes. There are 8 shades of red, 8 shades of green, and 4 shades of blue. The video board also contains circuitry (U34, U35, U36, U38, U49 and U50) to make the picture 'flip' for cocktail table models. The jumper platform at U12 must be installed for the video board to function properly. **DO NOT TAMPER WITH THESE JUMPERS.**

c) EPROM BOARD

The EPROM board is a relatively simple memory system. It has 23 2716 EPROMs totalling 46K bytes of memory (1 byte equals 8 bits). U24 and U30 decode all the EPROMs; U25 is the buffer IC to the data bus. In operation, any one of 23 EPROMs is selected by 5 CPU address lines.

d) SPEECH SYNTHESIS BOARD

The Speech Synthesis board contains a single-chip microcomputer (SCM), U14, an 8035. The SCM has all the basic elements of a computer, except for power, integrated in a single package. There are two main sections to the Speech Board. Section 1, schematic sheet 5, is the speech generation circuit. U7 is the system EPROM and contains all the basic programming for the 8035 CPU. The other EPROMs, U3 through U6, contain the speech information for Astro Blaster. U2 is the actual speech chip which synthesizes human speech. It operates by receiving the

data that compose speech patterns, combines them and outputs the sounds to amplifier U8 and to U11. Section 2, sheet 6, is mainly development circuitry; but, U21 is used in latching the proper 8-bit word from the CPU to select the different speech messages.

e) SOUND BOARD

The Astro Blaster G-80 Sound Board contains the circuits needed to generate all game sounds other than the speech. The Sound Board circuits are triggered through latches U32 and U33 which are connected to the data bus. The appropriate 8-bit code on the data bus is latched by U33 or U32 to activate the corresponding sound circuit. All sound board signals are mixed by IC U7 and output at P1-1. This output is again mixed with the speech sounds on the Speech Board through connector pin 1 and finally through U11. The final audio output is brought into the power supply amplifier.

2. Power Supply

The Game Power Supply (800-0128) incorporates all of the voltages and audio power amplification necessary to power Astro Blaster. In addition to the logic supply voltages available, 100 VAC and 115 VAC isolated supplies are available for the TV monitor and fluorescent lights. Also, multiple primary taps are available for using 100 VAC, 115 VAC, or 230 VAC as the input voltage.

This supply was originally designed for use with the Dual Game Board or Dual Game VIC Board. Table 1 lists the ratings of the supply when all outputs are used simultaneously. This also happens to be a standard test load. These are worst case ratings (such as when the PROMS in use draw their maximum rated currents) and therefore are rarely encountered when driving Dual Game Boards.

TABLE 1

+5 V @	2A	=	10W
-5 V @	1A	=	5W
+12 V @	1.5A	=	18W
-12 V @	1A	=	12W
MONITOR & LIGHT			
100 VAC or 115 VAC			75W
TOTAL			120W

The rating of the +5V supply can be safely increased to 3.5 amps if the load currents on the other voltages are reduced. This is necessary to prevent the heat sink and transformer temperatures from increasing to the point where reliability suffers.

a) Circuit Description: The +5 volt supply consists mainly of U1 and Q5. U1 is a 723 voltage regulator IC, which contains a voltage reference, error amplifier, series pass Darlington transistor pair and a current limit transistor. Potentiometer R5 (+5V ADJ) divides the 7.15V (nominal) reference to 5.0 volts as the input to pin 5, the non-inverting input of the 723's error amp. Pin 4, the inverting input, senses the output voltage. The internal error amp maintains a voltage at U1 pin 10 which is higher than the 5.0 V output by an amount equal to the two VBE drops of Darlington Q5, which acts as a current amplifier, and the IR drop across R32.

A foldback current limiter circuit is composed of R32, R2, R3, Q1 and the internal current limit transistor of U1. This circuit allows the regulator to operate normally until the load current increases

to the point where the voltage across R32 reaches the value which starts "turning on" the internal current limit transistor. This internal transistor reduces the output current of the regulator to a fraction of the "knee" current when the output is shorted to ground. This feature greatly reduces the power dissipated in Q5 when the output is accidentally short circuited. This action occurs so quickly during a short that fuse F1 should not blow. The value of the "knee" current can be increased or decreased by decreasing or increasing R3, respectively. Capacitors C4 and C5 frequency compensate the regulator so it won't oscillate, and C1 and C26 perform high frequency bypassing. Q1 is included for temperature compensation. Temperature variations of its emitter-base voltage closely match and cancel the base-emitter voltage of the internal current limit transistor. Therefore, the "knee" current of this regulator of about 6 amps stays quite constant over wide temperature variations. The short circuit current is less than 100 ma. The +12 volt regulator uses 7.15 volts as a reference. U2 compares this voltage with the voltage at the wiper of R23 (+12V ADJ). Darlington PNP Q6 is the series pass element: Transistor Q2 and current sense resistor R12 form the current limit circuit to protect Q6 from excessive load currents. The trip point is about 3 amps. Resistor R10 shuts the circuit off even harder if the output is short circuited. Resistor R11 and electrolytic C7 form a low pass filter which prevents short current pulses from activating the current limit circuit. The -5V and -12V regulators utilize three terminal ICs, 7905 and 7912, respectively. Capacitors C2, C3, C11 and C14 bypass high frequencies so that U4 and U5 won't oscillate.

The audio power amplifier is composed of op-amp U3 and transistors Q3, Q4, Q7 and Q8. U3 provides most of the voltage gain while the transistors supply most of the current gain. This amplifier differs from previous ones in that the output stage also exhibits a voltage gain of about 2 or so that the output can swing close to both power supply rails. This allows this amplifier to supply 36 watts into 4 ohms and 24 watts into 8 ohms. These values will be less if the +12 volt or -12 volt supplies are loaded significantly and/or the line voltage is less than 115 VAC. The overall voltage gain of the circuit is set by the ratio of R20 and R28. The actual value is:

$$\frac{R20}{R28} + 1 = \frac{47K}{2.2K} + 1 = 22.4 \text{ or } 27 \text{ db}$$

Capacitor C13 determines the low frequency roll off (about 7 HZ) and forces the DC gain to be unity. Therefore, the circuit does not amplify DC voltage. The input impedance is 47k ohms and is direct coupled.

b) Adjustments:

- i. Adjust R5 for 5.0V at the load. This compensates for wiring losses.
- ii. Adjust R23 for 12.0V at the load.
- iii. There are no adjustments for the -5V or -12V supplies or for the amplifier. The values should be -5V \pm 0.2V and -12V \pm 0.5V.

maintenance procedures

1. Self-Test

Astro Blaster contains a built-in self-test system, activated by depressing the red self-test switch located on the CPU board. If the cover to the G80 card cage is in place, the switch can be activated by putting a pen or pencil through the hole provided on the cover.

- a) CPU Board RAM Test — The first test performed is a CPU Board RAM test, for IC's U26-U29. It is instantaneous and ends when the screen goes white. If there is a problem in the CPU Board, the test will not continue, and you must use standard troubleshooting techniques to isolate and repair the CPU Board. There is a red LED, called the Halt Light, located directly behind the self-test switch. When a problem in the CPU occurs, it will come on and remain lit.
- b) Video RAM Test — The white screen is the beginning of the Video RAM test. If there is a problem here, the halt light comes on and flashes continuously. The screen displays:

CPU HALT VIDEO MEMORY
FAILED

CHIP U19

It tells you exactly which chip is defective. The rest of the test will not continue until the faulty RAM is repaired. If the video RAMs are functioning properly, the screen displays:

VIDEO MEMORY
TEST PASSED

- c) Input Test — The next sequence tests for errors in the input circuitry. The screen display is on the next page. INT in the upper left corner of the screen tests the interrupt circuits to the CPU. To be working properly, random characters should be displayed very rapidly to the right of INT. This shows the interrupt circuits are functioning properly. If the space to the right of INT remains blank, the CPU is not being interrupted properly. Dip Switch settings are displayed to verify the options selection. 1PSTART and 2PSTART will not be displayed on the screen initially. Depress the 1-player and 2-player buttons alternately and they should appear on the screen. If not, then there is a problem in the circuitry associated with the 1 and 2 player buttons. The bottom of the screen displays Player Controls. To be functioning correctly, they should all display OFF, then as each switch is depressed, display ON.

INPUT TEST									
INT	DIP SWITCHES								
	8	7	6	5	4	3	2	1	
1	0	0	0	0	0	0	0	0	
2	C	C	C	C	C	C	C	C	
1PSTART					2PSTART				
PLAYER CONTROLS									
P1 LEFT					OFF				
P1 RIGHT					OFF				
P1 FIRE					OFF				
P1 WARP					OFF				

- d) Coin Test — This test checks the timing of the coin switch. Refer to illustration below. To activate this test, insert coins into both coin mechs alternately. Coin mech 1 will appear on the screen as A and coin mech 2 will be displayed as B. Any letter appearing within the good area indicates the coin switches are timed properly. The closer the letter comes to either line, though, the more out of adjustment the coin switches are. Adjust a faulty coin switch by bending the trip wire up or down, slightly. To proceed to the next test, the 1-player button must be depressed.

COIN TEST		
BAD	GOOD	BAD
	A	
	A B	
	B	

- e) Eprom Test — This test checks PROMs in the entire system. Note the display above. The part number for each Eprom is displayed and whether that PROM is good or bad. This is a fast test and will not remain on the screen long if none of the PROMs are bad.

EPROM TEST	
0813	GOOD
0814	GOOD
0815	GOOD
0816	GOOD

0824	GOOD
0825	GOOD
0826	GOOD
0827	GOOD
0828	GOOD
****	NONE
****	NONE
****	NONE

- f) Screen Test — This test is a color test. A solid black box divided into 4 quadrants should appear on the screen. The upper left quarter displays eight shades of green. The upper right displays eight red shades and the lower left displays four blue. The lower right quarter should remain black. The shades of color are displayed as bars in each quarter. One of each shade is OFF or will appear to be black. This test must be terminated by depressing the 1-player button.
- g) Sound Test — The final phase displays each type of sound on the screen accompanied by the actual audio sound. It starts with the display, ALL SOUNDS OFF, and continues through seventeen different sounds. The final sequence is VOICE. The test runs through the entire Astro Blaster vocabulary.

At the conclusion of the sound test, the game returns to the advertising sequence and the test is completed.

game adjustments

1. Operator Panel

The operator panel is located on the inside of the coin door behind the coin mechanism. It contains the volume control for adjusting sound, a service switch for giving credits without increasing the coin counter and a reset switch for resetting the game.

2. Options Selection

The following charts define the game and coin/credit options available on the Astro Blaster game. These options are controlled by 2 sets of switches (DIP) located in the upper left hand corner of the G-80 CPU card. Switch #1 is positioned close to the edge of the board; switch #2 is recessed.
